

B1

a transistor having a data line, a gate electrode and a pixel electrode and comprising a layer of insulating material of the transistor situated between a first layer of conductive material of the transistor that forms the gate electrode and a second layer of conductive material of the transistor that forms the data line and pixel electrode, the transistor for applying an addressing voltage to the display medium by charging the pixel electrode during an addressing event having a duration that is insufficient to fully evolve the optical state of the display medium; and

a storage capacitor comprising a layer of insulating material of the storage capacitor situated between a first layer of conductive material of the storage capacitor and a second layer of conductive material of the storage capacitor, said storage capacitor in electrical communication with the display medium addressed by the transistor to apply an electric field to the display medium to continue evolving the optical state of the display medium after the addressing event.

---

18. (Twice Amended) An electrophoretic display comprising:

B2

a display medium comprising at least one capsule containing a plurality of electrophoretic particles dispersed in a fluid medium, wherein the plurality of electrophoretic particles move during evolution of an optical state of the display medium; and

a storage capacitor comprising a layer of insulating material situated between a first layer of conductive material and a second layer of conductive material, said storage capacitor in electrical communication with a pixel comprising a portion of the display medium to apply an electric field to the display medium to evolve the optical state of the pixel after a pixel addressing event.
